This is based on Ecological Site Classification (ESC) optimal National Vegetation Classification (NVC). It shows where tree species are best suited to the climate and soil types. The species are only indications of the main species, in reality the different zones will have mixtures of native species and open space. These trees will be established through natural regeneration so will have an irregular distribution, density and age range. Natural processes will allow gaps to be created and regenerate over time.

Scotland's national
forests and land
are responsibly
managed to the
UK Woodland
Assurance Standard.
